

RACO-ELECTRIC CYLINDER®

MODULAR SYSTEM – HEAVY DUTY SERIES (TYPE 1) SIZE 4,5,6,7,8

**HIGH-PERFORMANCE
ELECTRIC CYLINDERS:
ROBUST, RELIABLE AND FLEXIBLE
RETRO-FITTING**

The RACO actuator system is of modular design, and thus enables the combination of the most important integral elements of the electric cylinder such as the spindle-nut system, the gearbox, the electric motor and the sensors. This versatility opens up a wide range of applications for the RACO electric cylinder type 1.

Depending on the application in question, the suitable thrust-retraction unit of the electric cylinder can be equipped with a DC motor, AC motor, step motor or servo-motor. The performance data listed in the table refer to the version with a RACO 3-phase motor, which can be optionally fitted with a frequency converter. This motor can also be fitted with a parking brake and / or manual adjustment device.

In order to meet the requirements of every installation situation, various attachment points are provided on the electric cylinder for fitting to the construction or the on-site foundations.

All interfaces are provided for the adaptation of various sensor

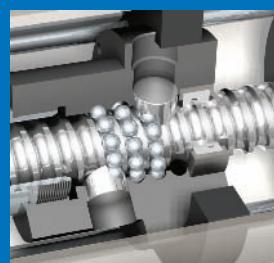

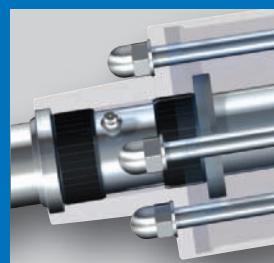

components such as limit switches, rotary impulse encoders, position transmitter, distance measurement systems and force measurement systems. The corresponding electronic assemblies are also available for the actuation of the electric cylinders.

The configuration of these proven components in accordance with specific customer technical conditions guarantees a high level of operating safety and reliability for every individual RACO electric cylinder.

Performance data, dimensions and weights for actuator size 4 (max. 2,5 kN) up to size 8 (max. 100 kN)

For technical details about size 9 (max. 160 kN) up to size 11 (max. 1000 kN) please refer to catalogue 3.1.1.

RACO-ELECTRIC CYLINDER®

MODULAR SYSTEM – HEAVY DUTY SERIES (TYPE 1) GENERAL INFORMATION

THE RACO ELECTRIC CYLINDER

The actuators of this series are very robust, and as a sealed system protected against the ingress of dirt are particularly suitable for use under high-stress conditions. Even under the most difficult conditions, constant stroke speed and high positioning accuracy is ensured. Many thousands of RACO electric cylinders have already proven themselves to remain highly accurate and reliable under extreme operating conditions such as heat, cold, dust and humidity.

Features & Benefits:

- High force, long stroke and high speed available to fit your individual needs
- Solid construction principle with high class material for all kinds of applications
- High reliability even under extreme operating conditions
- Highest positioning accuracy and reproduction of former values
- High shifting frequencies and high dynamic movement
- All sizes with trapezoidal, multiple-speed trapezoidal thread spindles or ball screws
- Long-term lubrication with internal grease depot for anticipated working life
- Totally enclosed system optional with special sealing and corrosion protection
- Many options for the actuator control

The mechanical thrust-retraction unit consists of a spindle-nut system with modified thrust tube, which is installed in a sealed housing. The cylinder housing is constructed of alloy or steel, depending on the size of the unit, and can optionally be given an inner coating for increased corrosion protection. The thrust tubes are coated with a special permanent hard-chrome plating, or are optionally available in stainless or rustproof material. Two standard **spindle types** are available for the spindle-nut system:

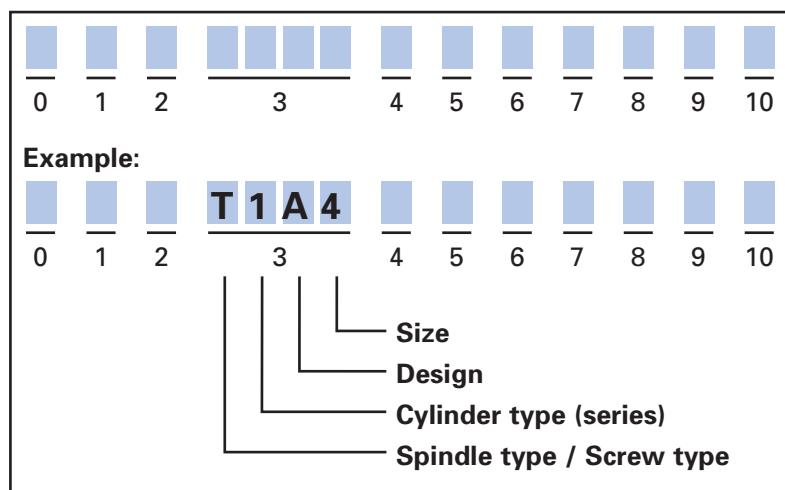

The **trapezoid threaded drive** consists of a spiral or optional ground spindle in combination with a spindle nut of special bronze. Depending on the choice of spindle geometry and drive, this version can also provide a self-restricting capability. Even high static stresses well above the nominal setting force can be reliably held in any intermediate position. Multiple

trapezoid spindles and / or larger spindle pitches can optionally be used in order to increase the setting speeds.

The **ball screw drive** has no self-restricting capability, since only little friction occurs between the nut and spindle due to the roller contact between the balls and runners. This causes less wear than in a threaded spindle, which under the same operating conditions therefore results in the longer working life of the ball threaded drive. This spindle type is therefore particularly suitable for applications requiring a high degree of precision for the positioning and repetition accuracy.

Depending on the installation position of the RACO motor, the modular design enables (with or without gearbox) 3 different **basic designs** (A/M = straight, C/N = parallel, T = angled).

Extract from the RACO type code:

RACO-ELECTRIC CYLINDER®

MODULAR SYSTEM – HEAVY DUTY SERIES (TYPE 1) TECHNICAL INFORMATION

Features:

- Screw incl. internal torque support of the nut
- Hard chromate plated push pull unit with rod eye clevis
- Front cap double sealed and with ice wiper
- AC motor or gear motor with brake
- Motor optional with hand wheel for manual emergency operation
- Limit switches and position transmitter in a sealed housing
- Integrated shock absorbing system and torque switch

RACO 3-phase motors

The electric cylinders are equipped with the latest generation of RACO motors, which are available as three-phase AC motors or as AC motors. The 2-, 4-, 6- and 8-polar motors are available in different designs and capacities up to 4.0 kW.

All RACO motors of this series are equipped with a thermo-contact and are suitable for frequency converter operation. Due to RACO's specific modular system a number of sensor options are additionally available to the user, thus enabling fine tuning of the motor to specific customer applications.

Motor performance / switching frequency

The motor performances for the operation in relation to the corresponding switching time are

listed in the tables for the electric cylinders with trapezoid or ball screw drive.

Since the electric cylinders with 3-phase motors are actuated in offset operation, the switching frequency in relation to permissible warming is decisive for the engineering and design.

Converter operation

In converter operation, it should be noted that as a result of the upper wave content of the voltage, the frequency converter leads to increased losses in the motor, which are all the lower the better the output voltage of the converter is adapted to the sinus form. Depending on the speed setting range, counter-torque progression, load play and converter type, the possible performance reduction and choice of cooling method must be taken into account. RACO motors should basically be operated as a maximum from 500 V, 50 Hz power supply systems, taking into account the voltage load on the insulation system by the converter.

The operating method of the motors in converter operation must be adapted to the non-ventilated design, i.e. higher load torques at low speeds can in the case of long running times lead to impermissible heating and actuation of the thermo-switch. The use of an optionally available thermistor is recommended. The corresponding type of operation should be taken into account in the form of higher designed performance or a ventilated version.

Position sensors

The electro-mechanical setting drives must not be moved to the mechanical end-position, but must be stopped reliably within the available usable stroke by the controls on reaching the end-position switches. For electric cylinders of cylinder type 1, additional equipment housings are available with up to 6 adjustable, mechanically operated change-over switches (Type: ME) and an electronic position encoder (Type: DMU) for signalling the end positions and / or intermediate positions.

Alternatively, RACO also offers a contactless, electronic sensor, which includes further functions in addition to the end-switch functionality. Two fixed positions can be specified by means of a "teach-in" mode with the aid of the electronic position sensor (Type: EPS02). In contrast to the basic variant, the electronic position sensor (Type: EPS06) offers 4 further switch functions, speed (revolutions) monitoring and an analogue signal for the actual position value. The impulses can also be evaluated in the same way as an incremental encoder. Exact modification of the drive to the customer application can quickly be carried out on site.

Force sensors

For the overload monitoring as well as security switch off a torque sensor can be implemented in the system on request.

RACO-ELECTRIC CYLINDER®

	1800	2380																			
	2000	2580																			

Note: For size 6 a stroke up to 2000mm is available! Any special stroke for all sizes on request. The stroke can be freely selected for all mentioned forces in combination with the corresponding speed.

Motor: The standard connection voltage is 230/400 V AC, 50 Hz! The basic version of the RACO motors of series 4 - 8 is the non-ventilated motor with B5-flange diameter of 140 mm or 200 mm at the front, and (brake) bearing plate at the rear for installation of other RACO devices. Metric threads for cable screw connections are provided in the junction box.

Protection type: All new RACO motors are supplied with IP 54 protection. Motors with increased protection types (IP 65) optional.

Note: Since the self-restricting capability of the electric cylinder with trapezoid thread drive can be cancelled out under certain circumstances, such as vertical installation with a suspended load and/or vibrations, a brake is recommended.

	2000	2580																		

Note: For size **6** a stroke up to 2000mm is available! Any special stroke for all sizes on request. The stroke can be freely selected for all mentioned forces in combination with the corresponding speed. * Not self-locking, brake "L" recommended. ** including end cover of 25mm, delete when accessory housings A, B or C are used, Length of motor without brake!

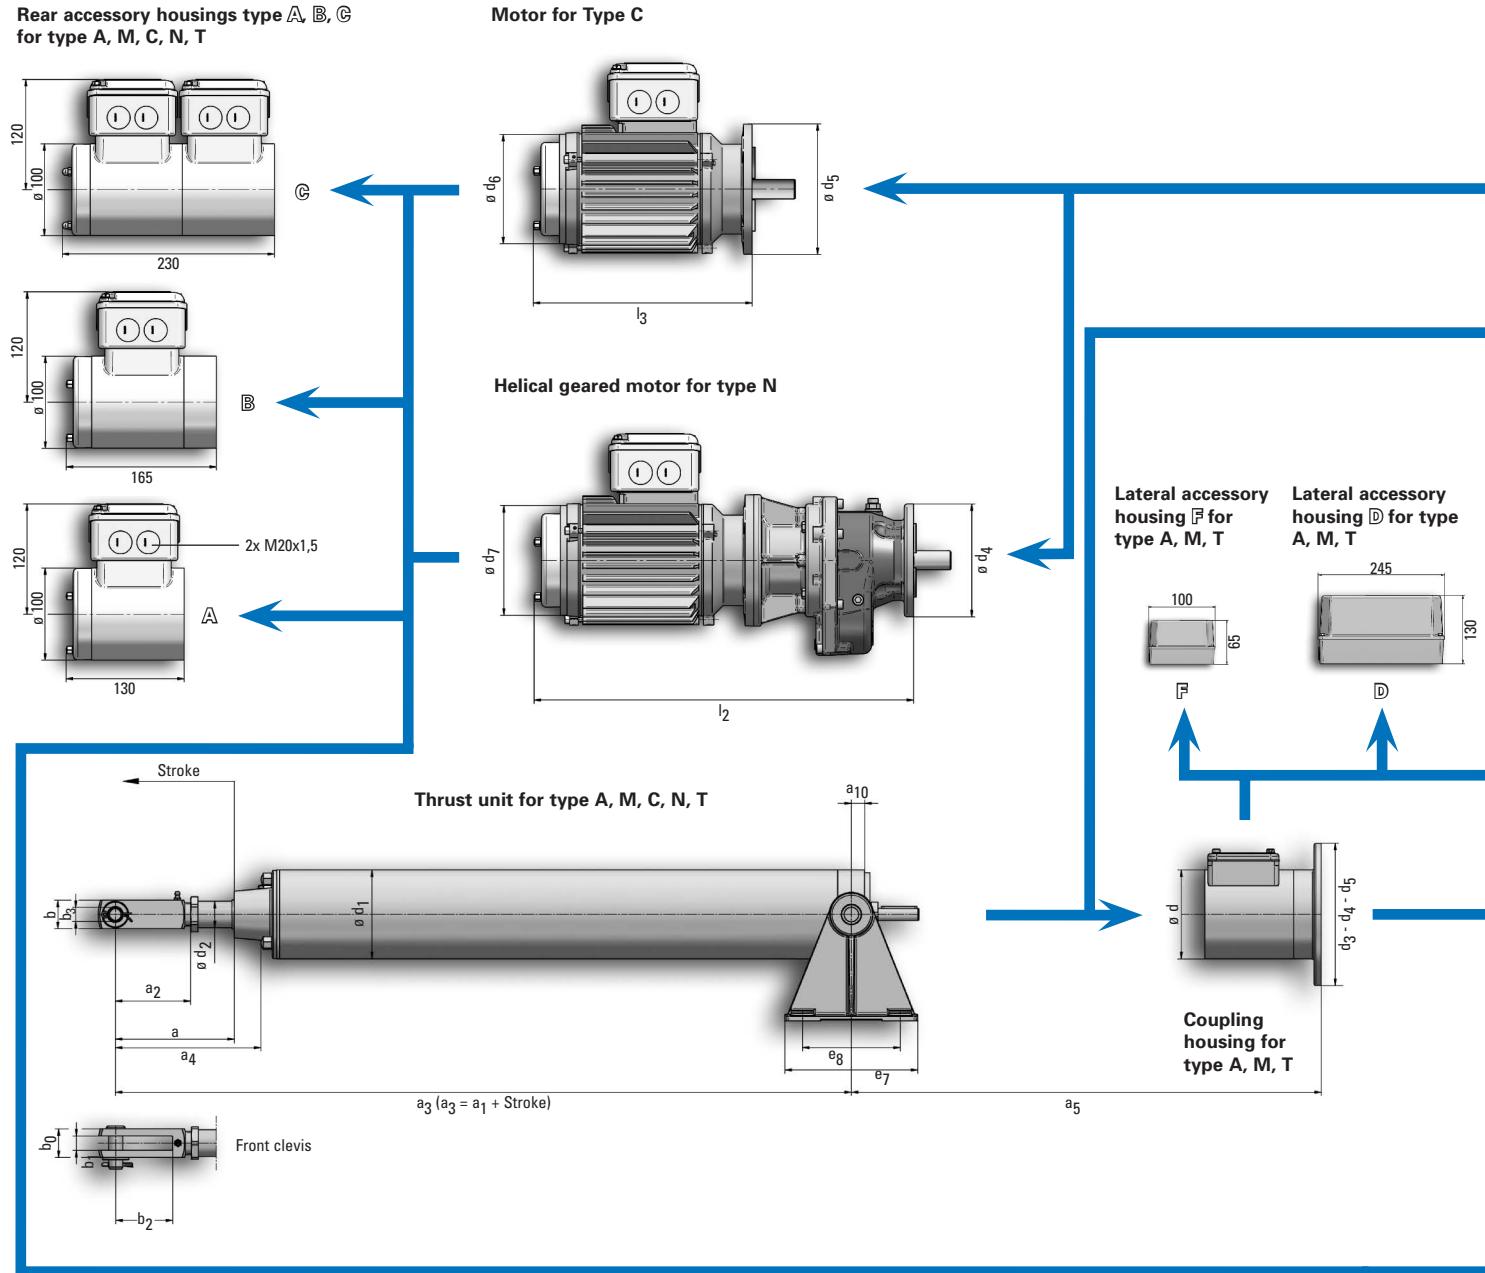

Insulation class: The insulation systems of machinery must be allocated to a heat class according to IEC 85. The motors are available in heat class F, or at an extra price in heat class H.

Special version: In the tropical protection version, the copper winding is impregnated with a special coating.

Note: Other performance data are also possible following review of specific customer requirements. At high setting speeds, the run-on, which affects the usable stroke, is reduced by means of a brake.
